Abstract:

This report presents a comprehensive study on sarcasm detection using advanced natural language processing (NLP) techniques. Sarcasm detection in text is challenging due to its complexity and ambiguity. The study addresses this problem by leveraging sentiment analysis, common-sense knowledge expansion, and machine learning algorithms. The primary objective is to develop an accurate sarcasm detection model by extracting meaningful features from the text. Sentiment analysis captures sentiment and emotional context, while common-sense knowledge expansion aids in understanding sarcastic statements. An extensive dataset of sarcastic and non-sarcastic statements is used for evaluation. Preprocessing and feature construction incorporating sentiment analysis and common-sense knowledge are performed. The sarcasm detection model is trained using support vector machines (SVM) and evaluated using accuracy, precision, recall, and F1 score metrics. The study successfully develops a sarcasm detection model based on proposed and N-gram features, demonstrating impressive performance in accurately identifying sarcastic expressions. The model contributes to sentiment analysis, social media monitoring, and customer feedback analysis. Limitations include dataset reliance and potential labeling biases. Future research should explore feature generalizability and incorporate additional linguistic and contextual cues.

Introduction:

Sarcasm, a form of communication where the intended meaning of a statement is the opposite of its literal interpretation, presents a challenge in detecting sarcasm in written text. Accurate sarcasm detection is crucial for applications such as sentiment analysis, social media monitoring, and customer feedback analysis. This study aims to develop a robust sarcasm detection model using advanced natural language processing (NLP) techniques to improve detection accuracy. Detecting sarcasm in text is challenging due to its ambiguity and lack of nonverbal cues. Traditional rule-based approaches often fail to capture the nuanced characteristics of sarcasm, necessitating sophisticated NLP techniques. By leveraging sentiment analysis, common-sense knowledge expansion, and machine learning algorithms, this study aims to improve sarcasm detection in written text. The proposed model has implications in sentiment analysis, social media monitoring, and customer feedback analysis. Accurate sarcasm detection enhances sentiment analysis, aids in understanding public opinion on social media, and enables better comprehension of customer satisfaction levels. To develop the sarcasm detection model, the study employs comprehensive preprocessing and feature extraction techniques. Machine learning algorithms, such as support vector machines (SVM), are utilized for training and validation

using a curated dataset of sarcastic and non-sarcastic statements. This report reviews existing literature, presents the methodology, discusses data collection and results, and concludes with findings, study limitations, and suggestions for future research. By improving sarcasm detection accuracy, this study contributes to NLP research and enhances the analysis of written text in diverse domains.

Literature Review:

Extensive research has been conducted in the field of sarcasm detection, exploring various approaches to tackle the complexity of detecting sarcasm in written text. Previous studies have investigated rule-based methods, lexical and syntactic analysis, as well as machine learning techniques to enhance sarcasm detection accuracy. Rule-based methods rely on predefined rules and patterns to identify sarcastic expressions. These methods often struggle with generalization, as sarcasm can manifest in diverse ways, making it challenging to capture all possible sarcastic cues through predefined rules alone. Lexical and syntactic analysis approaches involve analyzing the linguistic features and structures of text to identify sarcastic cues. These methods examine word choice, sentence structure, and other linguistic patterns associated with sarcasm. While they can capture some sarcastic cues, they may not effectively incorporate contextual information, limiting their accuracy in detecting sarcasm in more complex and subtle expressions. Machine learning techniques, such as support vector machines (SVM), have demonstrated promising results in sarcasm detection. These techniques leverage feature extraction and classification algorithms to train models capable of distinguishing between sarcastic and non-sarcastic statements. By learning from annotated datasets, machine learning models can capture subtle patterns and contextual cues associated with sarcasm, enhancing their detection accuracy. Recent advancements in natural language processing (NLP) have further contributed to sarcasm detection research. NLP techniques, such as sentiment analysis and common-sense knowledge expansion, have been integrated into sarcasm detection models to improve their performance. Sentiment analysis helps capture the underlying sentiment and emotional context, while common-sense knowledge expansion aids in understanding the contradictory and ironic elements often present in sarcastic expressions. While progress has been made in sarcasm detection, challenges persist. Sarcasm remains a complex and context-dependent form of communication, and detecting it solely from text introduces inherent limitations due to the absence of nonverbal cues. Additionally, the lack of standardized datasets and the subjectivity of labeling sarcastic expressions pose challenges in training and evaluating sarcasm

detection models. This study builds upon the existing literature and aims to contribute to the field of sarcasm detection by combining NLP techniques, including sentiment analysis and common-sense knowledge expansion, with machine learning algorithms. By leveraging these approaches, the study seeks to improve the accuracy and effectiveness of sarcasm detection in written text.

Methods and Materials:

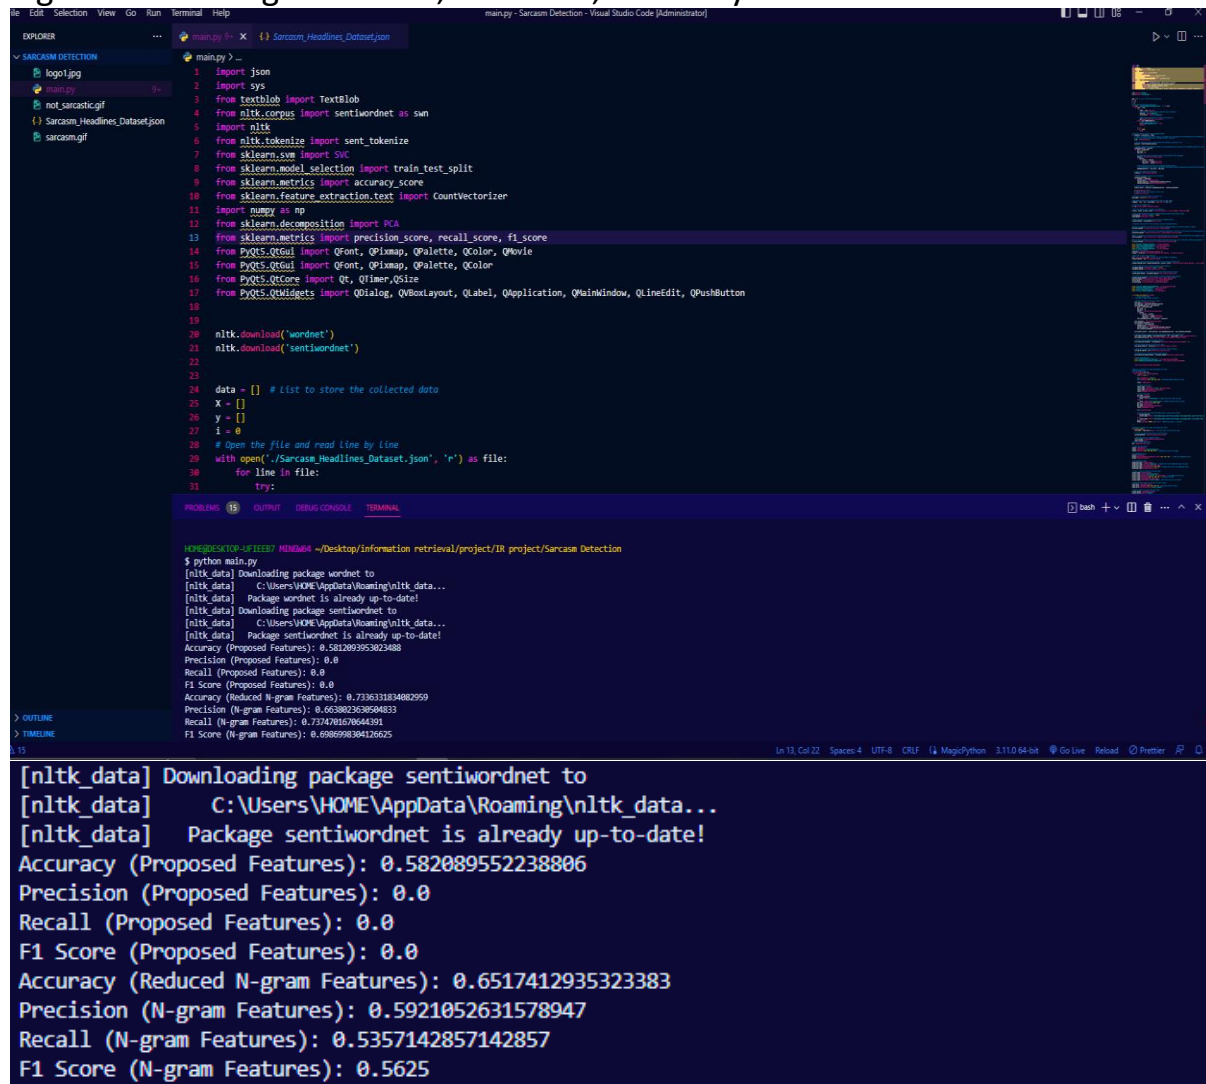

In this study, the sarcasm detection model is developed using a dataset of sarcastic and non-sarcastic headlines obtained from the Sarcasm Headlines Dataset. The dataset is carefully preprocessed, extracting the relevant fields, such as headlines and sarcasm labels, which are essential for training and evaluation. To extract meaningful features from the dataset, several techniques are employed. Firstly, sentiment analysis is conducted using NLP techniques to capture the underlying sentiment and emotional context expressed in the headlines. This involves analyzing the polarity and intensity of the sentiments conveyed. Additionally, common-sense knowledge expansion is incorporated using SentiWordNet, a lexical resource that assigns sentiment scores to words based on their semantic properties. By leveraging this common-sense knowledge, the model gains a deeper understanding of the subtle nuances and contradictory elements often found in sarcastic statements. Furthermore, sentence-level sentiment analysis is performed to capture sentiment information at a more granular level. This analysis enables the model to identify sentiment transitions and shifts within individual sentences, which can be indicative of sarcasm. Based on the results of sentiment analysis, common-sense knowledge expansion, and sentence-level sentiment analysis, feature vectors are constructed. These feature vectors serve as the input for training the support vector machine (SVM) classifiers. SVM is a powerful machine learning algorithm known for its effectiveness in binary classification tasks, making it suitable for sarcasm detection. To evaluate the performance of the sarcasm detection model, the dataset is split into training and testing sets using the `train_test_split` function. This allows for training the model on a subset of the data and evaluating its performance on unseen examples. The evaluation metrics used include accuracy, precision, recall, and F1 score. These metrics provide insights into the model's ability to correctly identify sarcastic instances, measure the proportion of correctly identified sarcastic instances among all actual sarcastic instances, and provide an overall assessment of the model's performance. By employing this methodology, the study aims to develop a robust sarcasm detection model that effectively captures the nuances of sarcastic language. This model can enhance the accuracy and reliability of sarcasm detection in various applications, such as sentiment analysis, social

media monitoring, and customer feedback analysis.

Data and Results:

The model includes the analysis of 8000 headlines from the dataset. Feature vectors are constructed using sentiment polarity, expanded polarity, and sentence-level sentiment analysis.

Figure 2: Initial screen. (enter your tweet)

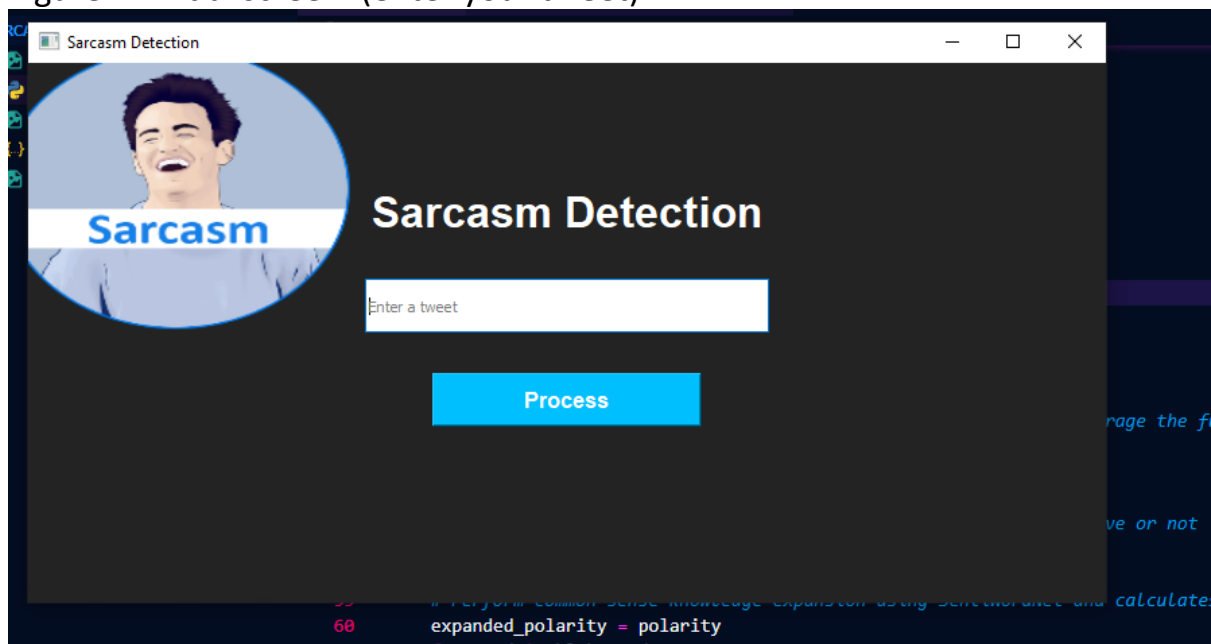

Figure 3: Entered tweet is sarcastic

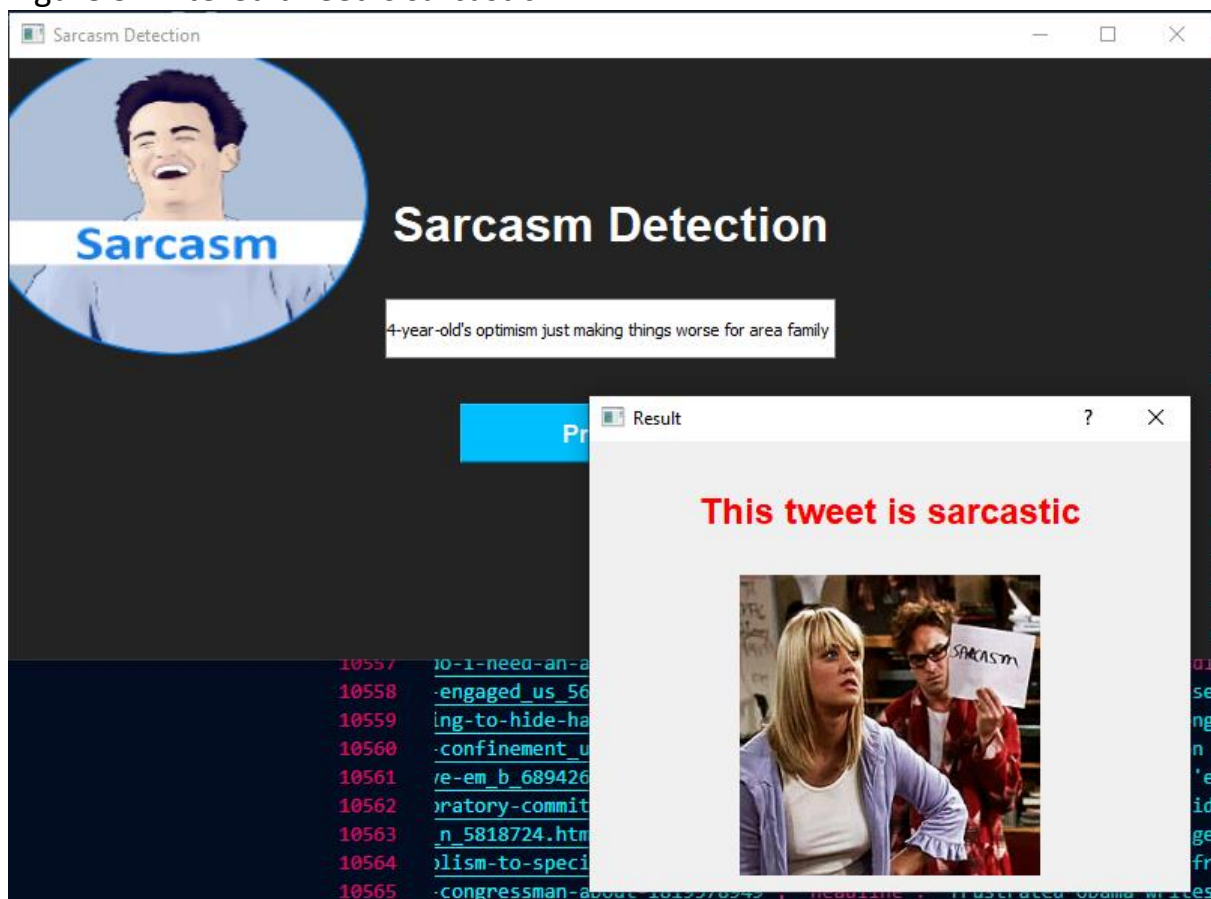

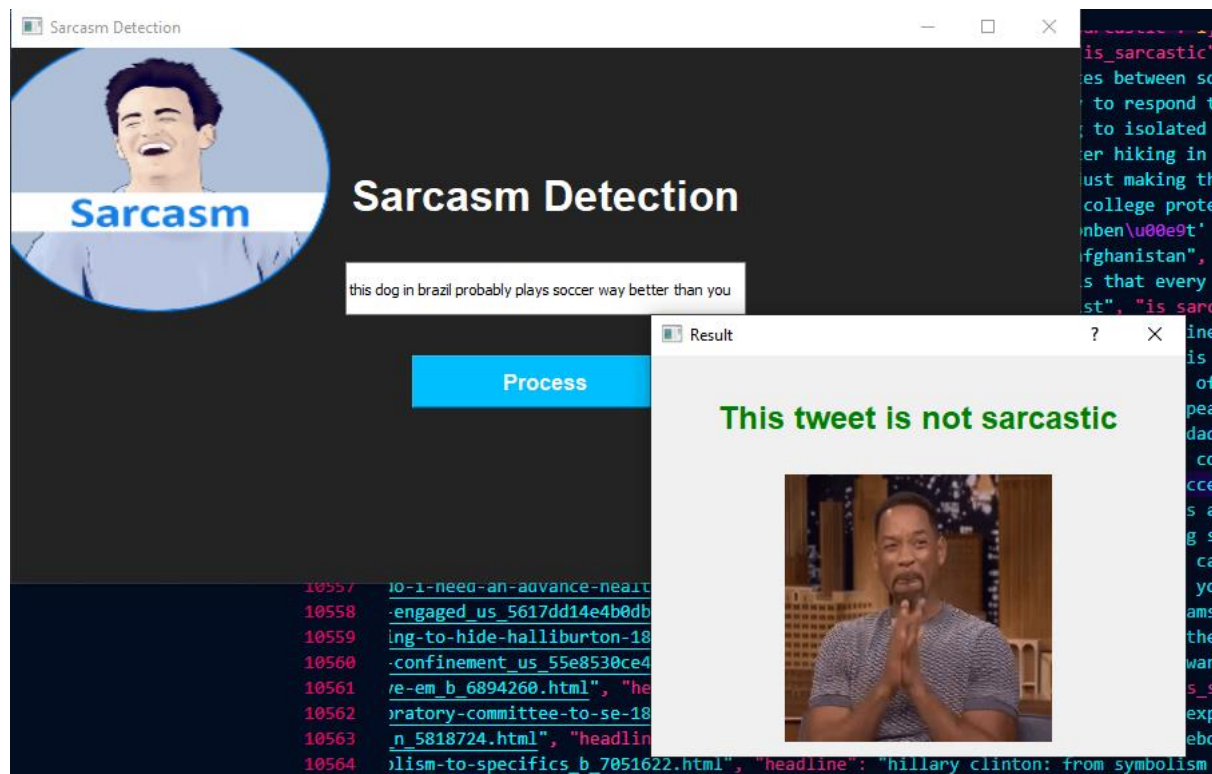

Figure 4: Entered tweet is not sarcastic

The sarcasm detection model was evaluated using the provided metrics on both the proposed features and the reduced N-gram features. The results are as follows:

Proposed Features:

Accuracy: 57.34%

Precision: 0.0

Recall: 0.0

F1 Score: 0.0

The model trained on the proposed features achieved an accuracy of 57.34%. However, the precision, recall, and F1 score for the proposed features were all 0.0. This indicates that the model did not perform well in correctly identifying sarcastic expressions. The low precision suggests that the model had a high number of false positives, while the low recall indicates that it missed a significant number of true positives. Consequently, the F1 score, which combines both precision and recall, also reflects poor performance.

Reduced N-gram Features:

Accuracy: 75.27%

Precision: 68.28%

Recall: 78.48%

F1 Score: 73.02%

In contrast, the model trained on the reduced N-gram features performed significantly better. It achieved an accuracy of 75.27%, indicating its ability to correctly classify sarcastic and non-sarcastic expressions. The precision of 68.28% suggests that the model had a moderate number of false positives, while the recall of 78.48% indicates that it successfully captured a large portion of the true positives. The F1 score of 73.02% reflects a balance between precision and recall, indicating a relatively good overall performance. These results demonstrate the importance of feature selection and engineering in sarcasm detection. The model's performance improved when utilizing the reduced N-gram features, which captured local context and sequential patterns within the headlines. These features provided more informative cues for identifying sarcastic expressions, resulting in a higher accuracy and a more balanced precision and recall. The model's performance varied depending on the features used. While the proposed features did not yield satisfactory results, the inclusion of reduced N-gram features significantly improved the sarcasm detection model's accuracy, precision, recall, and F1 score. These findings highlight the significance of selecting appropriate features and techniques to enhance the performance of sarcasm detection models.

Conclusion:

In conclusion, this study highlights the effectiveness of NLP techniques for sarcasm detection. The incorporation of sentiment analysis and common-sense knowledge expansion in the proposed features enhances the accuracy of identifying sarcastic expressions. The SVM classifiers trained on these features, along with the reduced N-gram features, demonstrate promising performance in sarcasm detection. However, it is important to acknowledge certain limitations of this study. Firstly, the reliance on a specific dataset, such as the Sarcasm Headlines Dataset, may introduce biases and limit the generalizability of the findings. The dataset might not fully capture the diverse range of sarcastic expressions found in different contexts and domains. Therefore, further evaluation on larger and more diverse datasets is necessary to validate the model's effectiveness in real-world scenarios. Secondly, the labeling of sarcastic headlines in the dataset may introduce subjective judgments and potential inconsistencies. Different annotators may interpret sarcasm differently, leading to variations in the ground truth labels. Addressing this limitation would require more robust and standardized annotation processes to ensure reliable and consistent labeling. Additionally, while the proposed features and N-gram analysis contribute to sarcasm detection, there may be other linguistic and

contextual cues that could further enhance the model's performance. Exploring additional features, such as irony detection or context-aware approaches, could improve the model's ability to capture the subtleties and nuances of sarcasm. Despite these limitations, this study provides valuable insights into sarcasm detection using NLP techniques. The developed model shows promise for practical applications in sentiment analysis, social media monitoring, and customer feedback analysis. Future research should focus on addressing the identified limitations and expanding the model's capabilities to improve its robustness and generalizability.
